Introduction

<ロト < 部 > < 目 > < 目 > 目 の Q () 3/28

- Language of "Web 2.0"
- Dynamic language used for large, structured web programs
- Supplanting Java applets, Flash

¹JavaScript is also known as ECMAScript, JScript $\square \rightarrow \langle \square \rangle \rightarrow \langle \square \rangle \rightarrow \langle \square \rangle \rightarrow \langle \square \rangle$

- Understand real-world patterns used in dynamic languages
- Do dynamic languages beget untypable code?
- Potential for type analysis of JavaScript
- What patterns in JavaScript could be recreated in a static context

- Extremely dynamic, flexible object system
- No static notion of type
- But is the dynamicity used?

Outline	Introduction	JavaScript	Measurements	Results	Conclusions

JavaScript

- Imperative, object-oriented
- Minimalistic standard library
- 3rd-party libraries abstract the type system (Prototype.js, jQuery, Ext)

- Objects have a prototype, which is another object
- Field lookup looks in the object itself, then its prototype
- Prototype chains act like subtype relationships

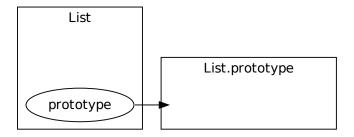

- Constructors have a prototype field, the prototype of objects created by the constructor: X.prototype is **not** the prototype of X, but the prototype of objects created by X
- The prototype of an object is accessible in many implementations by the field __proto__

Measurements

- Primary measurement is "dirtiness" of objects
- Dirtying actions:
 - Addition or deletion of a property
 - Update of a method
 - Update of the prototype field

 - Update of the prototype field
- Intuition:
 - "Clean" objects are nearly statically typable
 - "Dirty" objects use dynamic features
- Update of a field explicitly ignored

SunSpider tests

- Popular for benchmarking JavaScript implementations
- "(...) avoids microbenchmarks, and tries to focus on the kinds of actual problems developers solve with JavaScript today, (...)"
- Real web pages
 - Amazon, Basecamp, Facebook, Gmail, LivelyKernel, NASA
 - Random walk (normal web surfing activity)

Results -	— Objects				

- Results broken down by objects, in these categories:
 - Regular objects: objects created by new (and array literals.)
 - Constructors: functions used to create regular objects.
 - Functions: functions that are not used as a constructor.
 - Prototypes: objects created as prototypes of functions.

- Regular object dirtiness usually due to "optional" fields or object literals
 - v8-crypto: bignums constructor does not always create some fields; created instead by later functions such as fromInt
 - *v8-raytrace*: optional shader function added to some (but not all) objects

• In Gmail, 1896 prototype field updates, 1899 updates to constructors; strongly suggests class emulation

- Ratio of message sends to field updates
 - The vast majority of programs have a low ratio; used imperatively, not functionally
- Length of prototype chains
 - Max length 10 (gmail)
 - SunSpider's chains were all short (\leq 4)
 - $\bullet\,$ Real programs had greater max length (all $\geq 6)$
 - All programs had ≈ 2 average
- Calls to typeof
 - Rare in SunSpider, common in real programs
